

Causality

Pedro A. Ortega

Computational & Biological Learning Lab
University of Cambridge

18th February 2010

Why is causality important?

The future of machine learning is to **control** (the world).

Examples

- ▶ Classical example:

“Do smokers get lung cancer?” versus “Do smokers have lung cancer?”

- ▶ Programming:

$y \leftarrow f(x)$ versus $y = f(x)$.

- ▶ Physics:

$a \leftarrow \frac{F}{m}$ versus $F = ma$.

- ▶ Statistics is about measuring **correlation** of events.
- ▶ Causality is about the **functional dependency** of events.
- ▶ Most of science is driven by the need of **causal** understanding.

Why is causality . . .

. . . easy?

- ▶ It is intuitive: we reason in causal terms.
- ▶ Statistics can deal with it (given the right assumptions).

. . . difficult?

- ▶ Confounders impede the isolation of the functional dependency of interest.
- ▶ The concepts of causation are not fully formalized.
- ▶ Because it behaves like conditional probabilities under certain circumstances; in fact quite often because we tend to model causally!

Current status

- ▶ Historically studied by many philosophers (e.g. Hume).
- ▶ Banned from statistical vocabulary at the beginning of the 20th century (Pearson, Russell, ...).
- ▶ Exception: Randomized controlled trial (Fisher?).

Today, still in infancy state:

- ▶ Significant progress in causal understanding at beginning of the 90's.
- ▶ No consensus in formalization of causal notions.
- ▶ Many good (but confusing and mutually inconsistent) formalizations (Pearl, Spirtes, Shafer, Dawid, ...).
- ▶ No measure-theoretic formalization.
- ▶ But we are slowly getting there!
- ▶ Compare to the history of probability!

Barometer example

A barometer allows predicting the weather.

- ▶ If we **read** B , then can infer W . (Observation)

Barometer example

A barometer allows predicting the weather.

- ▶ If we **read** B , then can infer W . (Observation)
- ▶ If we **set** B , then we cannot infer W . (Intervention)
- ▶ We have to distinguish between **seeing** and **doing**.

Seeing versus doing

- ▶ Assume a circuit connecting **observable** quantities.
- ▶ Circuit represents a system **embedded** in Nature.
- ▶ Nature & system **determine** values of observable quantities.
- ▶ **No control** over the inputs \Rightarrow uncertainty.
- ▶ Statistician can act only **inside** of the system.

Seeing versus doing

- ▶ **Seeing = Observing = Measuring.**
- ▶ **Seeing** is the act of recording the value of observable quantities.
- ▶ **Seeing** is passive: the causal flow is undisturbed.
- ▶ Collected data allows constructing a truth table.

Seeing versus doing

- ▶ **Doing = Manipulating = Intervening.**
- ▶ **Doing** is the act of changing the functional dependency amongst observable quantities.
- ▶ **Doing** is active: the causal flow is disturbed.
- ▶ Knowing the blueprint is crucial to predict the resulting functional dependencies after interventions.

The essence of causal discovery

- ▶ How does X affect Y ?
- ▶ Collect data \implies obtain $P(X, Y) \implies$ compute $P(Y|X)$?

The essence of causal discovery

- ▶ How does X affect Y ? (← What does this even mean?)
- ▶ Collect data \implies obtain $P(X, Y) \implies$ compute $P(Y|X)$? **No!**
- ▶ **There might be a confounder!** What do we do now?

The essence of causal discovery

- ▶ How does X affect Y ? (← What does this even mean?)
- ▶ Collect data \implies obtain $P(X, Y) \implies$ compute $P(Y|X)$? **No!**
- ▶ **There might be a confounder!** What do we do now?
- ▶ Idea: decouple X from confounders.
- ▶ How: manipulate $X \implies$ intervene P (e.g. randomization).

The essence of causal discovery

- ▶ How does X affect Y ? (← What does this even mean?)
- ▶ Collect data \implies obtain $P(X, Y) \implies$ compute $P(Y|X)$? **No!**
- ▶ **There might be a confounder!** What do we do now?
- ▶ Idea: decouple X from confounders.
- ▶ How: manipulate $X \implies$ intervene P (e.g. randomization).
- ▶ But: Now P has changed into (say) Q !

Intervention of a probability distribution 1

Problem:

- ▶ If the intervention transforms P into Q , how can we ever say something about P using Q ?
- ▶ Under invariance assumptions, we can!

Intervention of a probability distribution 2

Example:

1. Determine the “blueprint”,

$$\begin{aligned}P(X, Y, Z) &= P(X)P(Y|X)P(Z|X, Y) \\ &= P(X)P(Y|X, Z)P(Z|X) \\ &= P(X|Y)P(Y)P(Z|X, Y) \\ &= P(X|Y, Z)P(Y)P(Z|Y) \\ &= P(X|Z)P(Y|X, Z)P(Z) \leftarrow \text{(causal decomposition)} \\ &= P(X|Y, Z)P(Y|X)P(Z)\end{aligned}$$

2. Replace $P(X|Z)$ by $Q(X)$:

$$Q(X, Y, Z) = Q(X)P(Y|X, Z)P(Z)$$

3. Collect data from $Q(X, Y, Z)$ and compute $Q(Y|X)$.

Intervention of a probability distribution 3

What have we achieved?

- ▶ Note that $Q(Y|X) \neq P(Y|X)$.
- ▶ By decoupling X from Z , we have **isolated the functional dependency** mapping X into Y .
- ▶ $Q(Y|X)$ reflects the right dependency, whereas $P(Y|X)$ doesn't!
- ▶ Analogy: we cannot understand the effect of X on Y in

$$Y \leftarrow f(X, Z)$$

if $X \leftarrow g(Z)$ in the collected data, because

$$Y \leftarrow f(X, g^{-1}(X)) = h(X),$$

and $h(X) \neq f(X, Z)$!

Stop.

Formalizations of causal inference 1

A non-exhaustive list:

- ▶ Pearl:
 - ▶ structural equations
 - ▶ represented in DAGs with causal meaning
 - ▶ do-calculus
- ▶ Dawid:
 - ▶ Augmented DAGs (influence diagrams)
 - ▶ decision variables determine regime of operation
- ▶ Shafer:
 - ▶ Probability tree
 - ▶ Moivrean events (sets of leaves) (=measure-theoretic events)
 - ▶ Humean events (sets of edges) (transformations)

Formalizations of causal inference 2

Causal DAG
(Pearl)

Augmented DAG
(Dawid)

Probability Tree
(Shafer)

Causality based on structural equations (Pearl)

Description

- ▶ Causal theory specifies:
 1. functional dependencies,
 2. probability distribution.
- ▶ Probabilities can be conditioned in two ways:
 1. evidential (Bayesian): $P(Y|X = x)$;
 2. interventional (causal): $P(Y|\text{do}(X = x))$.

Causal theory

- ▶ $\mathcal{X} = \{X_1, X_2, \dots, X_n\}$ (observed variables)
- ▶ $\mathcal{U} = \{U_1, U_2, \dots, U_m\}$ (unobserved variables)
- ▶ $P(\mathcal{U})$ (prob. over unobserved variables)
- ▶ $\mathcal{F} = \{X_i = f_i(\mathcal{X}, \mathcal{U})\}_{i=1}^n$ (inducing partial order over \mathcal{X})

Causality based on structural equations (Pearl)

Description

- ▶ Causal theory specifies:
 1. functional dependencies,
 2. probability distribution.
- ▶ Probabilities can be conditioned in two ways:
 1. evidential (Bayesian): $P(Y|X = x)$;
 2. interventional (causal): $P(Y|\text{do}(X = x))$.

Causal theory

- ▶ $\mathcal{X} = \{X_1, X_2, \dots, X_n\}$ (observed variables)
- ▶ $\mathcal{U} = \{U_1, U_2, \dots, U_m\}$ (unobserved variables)
- ▶ $P(\mathcal{U})$ (prob. over unobserved variables)
- ▶ $\mathcal{F} = \{X_i = f_i(\mathcal{X}, \mathcal{U})\}_{i=1}^n$ (inducing partial order over \mathcal{X})
- ▶ A causal theory can be represented as a DAG.

Example causal theory (Pearl)

$$X_1 = f_1(U_1)$$

$$X_2 = f_2(X_1, U_2)$$

$$X_3 = f_3(X_1, U_3)$$

$$X_4 = f_4(X_2, X_3, U_4)$$

$$X_5 = f_5(X_4, U_5)$$

The do-operator (Pearl)

- ▶ Handy notation for interventions that mimicks conditions.
- ▶ $do(X = x)$ means “replace the equation for X by $X = x$ ”.
- ▶ $do(X = x)$ corresponds to $Q(X) = \delta_x(X)$.
- ▶ Easy graphical interpretation (remove parent links).

Can we infer causal relations from observations?

- ▶ “To find out what happens if you kick the system, you have to kick the system.”
- ▶ Experiment is impossible or too costly.
- ▶ E.g. can we replace $P(Y|\text{do}(X = x))$ by $P(Y|X = x)$?
- ▶ Calculus to manipulate expressions with do-operations.

Can we infer causal relations from observations?

- ▶ “To find out what happens if you kick the system, you have to kick the system.”
- ▶ Experiment is impossible or too costly.
- ▶ E.g. can we replace $P(Y|\text{do}(X = x))$ by $P(Y|X = x)$?
- ▶ Calculus to manipulate expressions with do-operations.
- ▶ Do-calculus
- ▶ complete

Do-calculus (Pearl)

Let G be the causal DAG representing a causal theory.

Rules

- ▶ Insertion/deletion of observations:

$$P(y|\text{do}(x), z, w) = P(y|\text{do}(x), w) \quad \text{if} \quad (Y \perp\!\!\!\perp Z|X, W)_{G_{\bar{x}}}$$

- ▶ Action/observation exchange:

$$P(y|\text{do}(x), \text{do}(z), w) = P(y|\text{do}(x), z, w) \quad \text{if} \quad (Y \perp\!\!\!\perp Z|X, W)_{G_{\bar{x}, \underline{z}}}$$

- ▶ Insertion/deletion of actions:

$$P(y|\text{do}(x), \text{do}(z), w) = P(y|\text{do}(x), w) \quad \text{if} \quad (Y \perp\!\!\!\perp Z|X, W)_{G_{\bar{x}, \overline{Z(W)}}$$

where $Z(W)$ are Z -nodes not ancestors of W -nodes in $G_{\bar{x}}$.

Simpson's paradox

Two different recommendations with same data!

- ▶ Males and females take drug, then check recovery rate.

	Drug	No-drug
Males	18/30 (60%)	7/10 (70%)
Females	2/10 (20%)	9/30 (30%)
Totals	20/40 (50%)	16/40 (40%)

Simpson's paradox

Two different recommendations with same data!

- ▶ Males and females take drug, then check recovery rate.

	Drug	No-drug
Males	18/30 (60%)	7/10 (70%)
Females	2/10 (20%)	9/30 (30%)
Totals	20/40 (50%)	16/40 (40%)

- ▶ Patients take drug, blood pressure is measured, then check recovery rate.

	Drug	No-drug
High	18/30 (60%)	7/10 (70%)
Low	2/10 (20%)	9/30 (30%)
Totals	20/40 (50%)	16/40 (40%)

Simpson's paradox

Two different recommendations with same data!

- ▶ Males and females take drug, then check recovery rate.

	Drug	No-drug
Males	18/30 (60%)	7/10 (70%)
Females	2/10 (20%)	9/30 (30%)
Totals	20/40 (50%)	16/40 (40%)

- ▶ Patients take drug, blood pressure is measured, then check recovery rate.

	Drug	No-drug
High	18/30 (60%)	7/10 (70%)
Low	2/10 (20%)	9/30 (30%)
Totals	20/40 (50%)	16/40 (40%)

- ▶ First case: consult separate tables.
- ▶ Second case: consult aggregated table.

Simpson's paradox 2

Why?

- ▶ There is a confounder!
- ▶ The correct probability to compute is $P(R|\text{do}(D))$.
- ▶ The two cases have different causal models.
- ▶ For the second case: $P(R|\text{do}(D)) = P(R|D)$.

Simpson's paradox 3

1. Assumptions:

$$P(R|\text{do}(D), F) < P(R|\text{do}(\neg D), F)$$
$$P(R|\text{do}(D), \neg F) < P(R|\text{do}(\neg D), \neg F)$$

2. From intervened graph:

$$P(F|\text{do}(D)) = P(F|\text{do}(\neg D)) = P(F)$$

3. Calculating:

$$P(R|\text{do}(D)) = P(R|\text{do}(D), F)P(F|\text{do}(D)) + P(R|\text{do}(D), \neg F)P(\neg F|\text{do}(D))$$
$$= P(R|\text{do}(D), F)P(F) + P(R|\text{do}(D), \neg F)P(\neg F)$$
$$P(R|\text{do}(\neg D)) = P(R|\text{do}(\neg D), F)P(F) + P(R|\text{do}(\neg D), \neg F)P(\neg F)$$

4. Using the assumptions:

$$P(R|\text{do}(D)) < P(R|\text{do}(\neg D)).$$

Conclusions

- ▶ Causality is about **functional dependencies**.
- ▶ Understanding functional dependencies is essential for **control**.
- ▶ **Ask the right question:**
correlation or functional dependency?
- ▶ Key operation to isolate functional dependencies:
decoupling of control variables (doing).
- ▶ There are causal formalisms that work in practice!

Questions?
